"The profound study of nature is the most fertile source of mathematical discovery." JOSEPH FOURIER

A trigonometric basis

Let $n \in \mathbf{Z}_{\geq 0}$ and let $a_0, \ldots, a_n$ and $b_1, \ldots, b_n$ be real numbers. Define a function F by

$$F(x) = a_0 + \sum_{k=1}^{n} a_k \cos(kx) + b_k \sin(kx).$$

Expressing cos and sin in exponential form, the formula is

$$\begin{aligned} F(x) &= a_0 + \sum_{k=1}^{n} a_k \frac{\mathrm{cis}(kx) + \overline{\mathrm{cis}(kx)}}{2} + b_k \frac{\mathrm{cis}(kx) - \overline{\mathrm{cis}(kx)}}{2\mathrm{i}}, \\ &= a_0 + \sum_{k=1}^{n} \frac{1}{2}(a_k - \mathrm{i} b_k)\mathrm{cis}(kx) + \frac{1}{2}(a_k + \mathrm{i} b_k)\overline{\mathrm{cis}(kx)}. \end{aligned}$$

An exponential basis

So

$$F(x) = a_0 + \sum_{k=1}^{n} \frac{1}{2}(a_k - \mathrm{i}b_k)\mathrm{cis}(kx) + \frac{1}{2}(a_k + \mathrm{i}b_k)\overline{\mathrm{cis}(kx)}$$
$$= a_0 + \mathrm{Re}\left(\sum_{k=1}^{n}(a_k - \mathrm{i}b_k)\mathrm{cis}(kx)\right)$$

Defining complex numbers $c_0, c_1, \ldots, c_n$ as

$$c_k = \begin{cases} a_0 & k = 0 \\ a_k - \mathrm{i}b_k & k \neq 0 \end{cases}$$

we have

$$F(x) = \mathrm{Re}\left(\sum_{k=0}^{n} c_k \, \mathrm{cis}(kx)\right).$$

Unreal functions

If we drop the condition that F is real-valued and use the fact that $\overline{\operatorname{cis}(kx)} = \operatorname{cis}(-kx)$ we have

$$\begin{aligned} F(x) &= a_0 + \sum_{k=1}^{n} \frac{1}{2}(a_k - \mathrm{i}b_k)\operatorname{cis}(kx) + \frac{1}{2}(a_k + \mathrm{i}b_k)\operatorname{cis}(-kx), \\ &= \sum_{k=-n}^{n} c_k \operatorname{cis}(kx). \end{aligned}$$

where

$$c_k = \begin{cases} \frac{1}{2}(a_k + \mathrm{i}b_k) & k < 0 \\ a_0 & k = 0 \\ \frac{1}{2}(a_k - \mathrm{i}b_k) & k > 0 \end{cases}.$$

Unreal and orthogonal

For any $n \in \mathbf{Z}_{\geq 0}$, the set of functions

$$\{x \in [0, 2\pi] \mapsto \operatorname{cis}(kx) \mid k \in -n \dots n\}$$

is orthogonal with respect to the inner product

$$\langle f, g \rangle = \int_0^{2\pi} \overline{f(x)} g(x) \, \mathrm{d}x.$$

In particular for $k, \ell \in \mathbf{Z}$, we have

$$\int_0^{2\pi} \overline{\operatorname{cis}(kx)} \operatorname{cis}(\ell x) \mathrm{d}x = \begin{cases} 0 & k \neq \ell \\ 2\pi & k = \ell \end{cases} = 2\pi \delta_{k,\ell}$$

The Kronecker delta function

We define the Kronecker delta function δ as

$$\delta_{k,\ell} = \begin{cases} 0 & k \neq \ell \\ 1 & k = \ell \end{cases}.$$

- The arguments to the Kronecker delta are almost always subscripts.
- Example $\delta_{\pi,3} = 0$ and $\delta_{\pi,\pi} = 1$.
- We have $\sum_{k=0}^{n} f_k \delta_{k\ell} = \begin{cases} f_\ell & \ell \in 0 \ldots n \\ 0 & \ell \notin 0 \ldots n \end{cases}.$

A trigonometric puzzle

Problem Let $n \in \mathbf{Z}_{\geq 0}$ and let $c_{-n}, \ldots, c_n \in \mathbf{C}$. Define a function F whose formula is

$$F(x) = \sum_{k=-n}^{n} c_k \mathrm{e}^{\mathrm{i}kx}$$

For a given function F, we would like to find a way to find the complex numbers $c_{-n}, \ldots, c_n$.

Step #1

Step #1 Multiply $F(x) = \sum_{k=-n}^{n} c_k \mathrm{e}^{\mathrm{i}kx}$ by $\mathrm{e}^{-\mathrm{i}\ell x}$. This gives

$$\mathrm{e}^{-\mathrm{i}\ell x} F(x) = \sum_{k=-n}^{n} c_k \mathrm{e}^{-\mathrm{i}\ell x} \mathrm{e}^{\mathrm{i}kx} \tag{1}$$

Using a rule of exponents, we have

$$\mathrm{e}^{-\mathrm{i}\ell x} F(x) = \sum_{k=-n}^{n} c_k \mathrm{e}^{-\mathrm{i}(k-\ell)x}. \tag{2}$$

Step #2

Step #2 Integrate with respect to x over the interval $[0, 2\pi]$

$$\int_0^{2\pi} \mathrm{e}^{-\mathrm{i}\ell x} F(x)\,\mathrm{d}x = \int_0^{2\pi} \sum_{k=-n}^{n} c_k \mathrm{e}^{-\mathrm{i}(k-\ell)x}\,\mathrm{d}x. \tag{3}$$

Swap the integration and the finite sum:

$$\int_0^{2\pi} \mathrm{e}^{-\mathrm{i}\ell x} F(x)\,\mathrm{d}x = \sum_{k=-n}^{n} c_k \int_0^{2\pi} \mathrm{e}^{-\mathrm{i}(k-\ell)x}\,\mathrm{d}x. \tag{4}$$

Step #3

Step #3 Integrate the orthogonal functions:

$$\int_0^{2\pi} \mathrm{e}^{-\mathrm{i}\ell x} F(x)\,\mathrm{d}x = \sum_{k=-n}^{n} c_k 2\pi \delta_{k,\ell}. \tag{5}$$

Simplify the sum

$$\int_0^{2\pi} \mathrm{e}^{-\mathrm{i}\ell x} F(x)\,\mathrm{d}x = 2\pi c_\ell. \tag{6}$$

What did we just do?

We've shown that if

$$F(x) = \sum_{k=-n}^{n} c_k \mathrm{e}^{\mathrm{i}kx} \tag{7}$$

Then for all $\ell \in -n \dots n$, we have

$$c_\ell = \frac{1}{2\pi} \int_0^{2\pi} \mathrm{e}^{-\mathrm{i}\ell x} F(x) \, \mathrm{d}x \tag{8}$$

- Given the function F, the complex numbers c_{-n} through c_n are uniquely determined.

The Fourier coefficients

For any function F that is integrable on the interval $[0, 2\pi]$ the numbers c_k defined as

$$c_k = \frac{1}{2\pi} \int_0^{2\pi} \operatorname{cis}(kx) F(x) \, \mathrm{d}x$$

are the *Fourier coefficients* of the function F. Generally $k \in \mathbf{Z}$.

I know what you are thinking

Unless F is fairly simple, we have no chance at finding a formula for the numbers c_{-n} through c_n.

Have no fear: we have a tool for that. Let's use the right-point rule integration to find approximate values for the Fourier coefficients. Using n equal length subintervals of $[0, 2\pi]$, we have

$$\begin{aligned} c_\ell &\approx \frac{1}{2\pi}\frac{2\pi}{n}\sum_{k=0}^{n-1} \mathrm{e}^{-\mathrm{i}\frac{2\pi}{n}\ell k} F(x_k) \\ &= \frac{1}{n}\sum_{k=0}^{n-1} \mathrm{e}^{-\mathrm{i}\frac{2\pi}{n}\ell k} F\left(\frac{2\pi}{n}k\right) \end{aligned}$$

Caveat

For large values of the integer ℓ, the integrand of

$$c_\ell = \frac{1}{2\pi} \int_0^{2\pi} \mathrm{e}^{-\mathrm{i}\ell x} F(x) \, \mathrm{d}x$$

becomes more and more "wiggly." So we should expect that our right point rule quadrature rule will give less and less accurate results for larger and larger ℓ.

Nice coincidence

You might be thinking “Why the low accuracy right point rule?” Why not something like the trapezoidal rule? Ha!

For a function F with period 2π, the right-point, left-point, and trapezoidal rule all give the same value for

$$\int_0^{2\pi} \operatorname{cis}(kx) F(x) \, \mathrm{d}x \tag{9}$$

where $k \in \mathbf{Z}$.

DFT defined

Definition Let $a_0, a_1, \dots a_{n-1}$ be numbers (either real or complex). For every $\ell \in 0 \dots, n-1$, define

$$\widehat{a}_\ell = \sum_{k=0}^{n-1} \mathrm{e}^{-\mathrm{i}\frac{2\pi}{n}\ell k} a_k$$

The list of numbers $\widehat{a}_0, \widehat{a}_1, \dots, \widehat{a}_{n-1}$ is the *discrete Fourier transform* (DFT) of $a_0, a_1, \dots, a_{n-1}$.

Doubly indexed things are matrices

For any $n \in \mathbf{Z}_{>0}$, define $\mathcal{F}_{\ell,k} = \mathrm{e}^{-\mathrm{i}\frac{2\pi}{n}\ell k}$. We have

$$\widehat{a}_\ell = \sum_{k=0}^{n-1} \mathcal{F}_{\ell,k} a_k$$

we see that the DFT is matrix multiplication. Arranging $\widehat{a}_0, \ldots \widehat{a}_{n-1}$ and $a_0, \ldots \widehat{a}_{n-1}$ as column vectors $\mathbf{a}$ and $\widehat{\mathbf{a}}$, respectively, we have

$$\widehat{\mathbf{a}} = \mathcal{F}\,\mathbf{a}$$

Magic properties

- When the size of a matrix $\mathcal{F}$ is $n \times n$, ordinarily the effort required to do the matrix product $\mathcal{F}\,\mathbf{a}$ is proportional to n^2.
- But the matrix $\mathcal{F}$ has some special (almost magic) properties that makes the effort only proportional to $n \log_{10}(n)$.
- The algorithm that utilizes these properties to perform the multiplication quickly is the *Fast Fourier Transform* (FFT).
- The FFT isn't really a transform, but an algorithm that computes a transform.
- When n is large, $n^2 \gg n \log_{10}(n)$.

What does chatGPT have to say?

Question Would this document make for a good lecture for 3rd year computer science students?

Answer Yes, this document could serve as a good lecture for 3rd year computer science students, particularly those interested in topics related to mathematics, signal processing, or algorithms. (Specifics deleted).
